Ref. By: Dr. DR AIIMS DELHI

Investigation: MRI Orbits with contrast.

Results: Multiplanar MR images of the orbits were obtained using T1, T2 weighted TSE SPIR sequences. Post contrast study was also performed.

The study reveals a linear structure extending from the posterior aspect of the lens to the optic disc of intermediate signal intensity on the T1W and T2W images and showing enhancement on the post contrast scans. There is an enhancing retrolental triangular soft tissue and enhancing membranes posterior to the lens and in the vitreous. Enhancing soft tissue of intermediate signal intensity on T1W and T2W images is seen in the medial aspect of globe abutting the retina in contiguity with these membranes measuring approximately 1.1 cm (AP) x 0.7 cm (TR) x 0.8 cm (CC).

The Vitreous appears mildly hyperintense on the T1W/T2 TIRM sequences.

The right globe appear normal in size, shape with homogenous contents.

The lens on either side appears normal in size, shape and position.

The extra-ocular muscles are normal in size, shape and signal.

The optic nerve is intact on either side.

The retro-orbital fat on either side is normal.

#### IMPRESSION:

MRI findings reveal an enhancing membrane extending from the posterior aspect of the lens to the optic disc with associated enhancing triangular retrolental soft tissue and membranes in the vitreous. There is an enhancing soft tissue in the medial aspect of the globe abutting the retina in contiguity with these membranes. The Vitreous appears mildly hyperintense on the T1W/T2W TIRM sequences suggesting possibility of haemorrhage/ proteinaceous contents.

In view of the above mentioned findings- Possibility of Persistent hyperplastic primary vitreous remains a differential. This will need correlation with Clinical findings, fundus examination, B scan findings and a NCCT study (to see for calcifications) for possibility of Retinoblastoma.

Please correlate clinically.
